## COST FUNCTIONS

## 1. Introduction to the Cost Function

1.1. Understanding and representing technology. Economists are interested in the technology used by the firm. This is usually represented by a set or a function. For example we might describe the technology in terms of the input correspondence which maps output vectors in $R_{+}^{m}$ into subsets of $2^{R_{+}^{n}}$. These subsets are vectors of inputs that will produce the given output vector. This correspondence is given by

$$
\begin{equation*}
V: R_{+}^{m} \rightarrow 2^{R_{+}^{n}} \tag{1}
\end{equation*}
$$

Alternatively we could represent the technology by a function such as the production function $y=f\left(x_{1}\right.$, $\mathrm{x}_{2}, \ldots, \mathrm{x}_{n}$ )

We typically postulate or assume certain properties for various representations of technology. For example we typically make the following assumptions on the input correspondence.
1.1.1. V. 1 No Free Lunch.
a: $\mathrm{V}(0)=R_{+}^{n}$
b: $0 \notin \mathrm{~V}(\mathrm{y}), \mathrm{y}>0$.
1.1.2. V.2 Weak Input Disposability. $\forall y \in R_{+}^{m}, x \in V(y)$ and $\lambda \geq 1 \Rightarrow \lambda x \in V(y)$
1.1.3. V.2.S Strong Input Disposability. $\forall y \in R_{+}^{m} x \in V(y)$ and $x^{\prime} \geq x \Rightarrow x^{\prime} \in V(y)$
1.1.4. V. 3 Weak Output Disposability. $\forall y \in R_{+}^{m} V(y) \subseteq V(\theta y), 0 \leq \theta \leq 1$.
1.1.5. V.3.S Strong Output Disposability. $\forall y, y^{\prime} \in R_{+}^{m}, y^{\prime} \geq y \Rightarrow V\left(y^{\prime}\right) \subseteq V(y)$
1.1.6. V. 4 Boundedness for vector $y$. If $\left\|y^{\ell}\right\| \rightarrow+\infty$ as $\ell \rightarrow+\infty$,

$$
\cap_{\ell=1}^{+\infty} V\left(y^{\ell}\right)=\emptyset
$$

If y is a scalar,

$$
\bigcap_{y \in(0,+\infty)} V(y)=\emptyset
$$

1.1.7. V.5 $T(x)$ is a closed set. $\mathrm{V}: R_{+}^{m} \rightarrow 2_{+}^{R}$ is a closed correspondence.
1.1.8. V. 6 Attainability. If $\mathrm{x} \in \mathrm{V}(\mathrm{y}), \mathrm{y} \geq 0$ and $\mathrm{x} \geq 0$, the ray $\{\lambda \mathrm{x}: \lambda \geq 0\}$ intersects all $\mathrm{V}(\theta \mathrm{y}), \theta \geq 0$.
1.1.9. V.7 Quasi-concavity. V is quasi-concave on $R_{+}^{m}$ which means $\forall \mathrm{y}, \mathrm{y}^{\prime} \in R_{+}^{m}, 0 \leq \theta \leq 1, \mathrm{~V}(\mathrm{y}) \cap \mathrm{V}\left(\mathrm{y}^{\prime}\right) \subseteq$ $\mathrm{V}\left(\theta \mathrm{y}+(1-\theta) \mathrm{y}^{\prime}\right)$
1.1.10. V. 8 Convexity of $V(y) . \mathrm{V}(\mathrm{y})$ is a convex set for all $\mathrm{y} \epsilon R_{+}^{m}$
1.1.11. V. 9 Convexity of $T(x)$. V is convex on $R_{+}^{m}$ which means $\forall \mathrm{y}, \mathrm{y}^{\prime} \in R_{+}^{m}, 0 \leq \theta \leq 1, \theta \mathrm{~V}(\mathrm{y})+(1-\theta) \mathrm{V}\left(\mathrm{y}^{\prime}\right) \subseteq$ $\mathrm{V}\left(\theta \mathrm{y}+(1-\theta) \mathrm{y}^{\prime}\right)$
1.2. Understanding and representing behavior. Economists are also very interested in the behavioral relationships that arise from firms' optimizing decisions. These decisions result in reduced form expressions such as supply functions $y^{*}=x(p, w)$, input demands $x^{*}=x(p, w)$, or Hicksian (cost minimizing) demand functions $\mathrm{x}^{*}=\mathrm{x}(\mathrm{w}, \mathrm{y})$. One of the most basic of these decisions is the cost minimizing decision.

## 2. THE COST FUNCTION AND ITS PROPERTIES

2.1. Definition of cost function. The cost function is defined for all possible output vectors and all positive input price vectors $w=\left(w_{1}, w_{2}, \ldots, w_{n}\right)$. An output vector, $y$, is producible if $y$ belongs to the effective domain of $\mathrm{V}(\mathrm{y})$, i.e,

$$
\operatorname{Dom} V=\left\{y \in R_{+}^{m}: V(y) \neq \emptyset\right\}
$$

The cost function does not exist it there is no technical way to produce the output in question. The cost function is defined by

$$
\begin{equation*}
C(y, w)=\min _{x}\{w x: x \in V(y)\}, \quad y \in \operatorname{Dom} V, w>0 \tag{2}
\end{equation*}
$$

or in the case of a single output

$$
\begin{equation*}
C(w, y)=\min _{x}\{w x: f(x) \geq y\} \tag{3}
\end{equation*}
$$

The cost function exists because a continuous function on a nonempty closed bounded set achieves a minimum in the set (Debreu [6, p. 16]). In figure 1, the set $V(y)$ is closed and nonempty for $y$ in the producible output set. The function $w x$ is continuous. Because $V(y)$ is non-empty if contains at least one input bundle $x^{\prime}$. We can thus consider cost minimizing points that satisfy $w x \leq w x^{\prime}$ But this set is closed and bounded given that $w$ is strictly positive. Thus the function $w x$ will attain a minimum in the set at $x^{\prime \prime}$.
2.2. Solution to the cost minimization problem. The solution to the cost minimization problem 2 is a vector $x$ which depends on output vector $y$ and the input vector $w$. We denote this solution by $x(y, w)$. This demand for inputs at for a fixed level of output and input prices is often called a Hicksian demand curve.

### 2.3. Properties of the cost function.

2.3.1. C.1.1. Non-negativity: $C(y, w) \geq 0$ for $w>0$.
2.3.2. C.1.2. Nondecreasing in $w$ : If $w \geq w^{\prime}$ then $C(y, w) \geq C\left(y, w^{\prime}\right)$
2.3.3. C.2. Positively linearly homogenous in w

$$
C(y, \lambda w)=\lambda C(y, w), \quad w>0
$$

2.3.4. C.3. C is concave and continuous in w
2.3.5. C.4.1. No fixed costs: $\mathrm{C}(0, \mathrm{w})=0, \forall \mathrm{w}>0$. We sometimes assume we have a long run problem.
2.3.6. C.4.2. No free lunch: $C(y, w)>0, w>0, y>0$.
2.3.7. C.5. Nondecreasing in y (proportional): $C(\theta y, w) \leq C(y, w), 0 \leq \theta \leq 1, w>0$.
2.3.8. C.5.S. Nondecreasing in $y: C\left(y^{\prime}, w\right) \leq C(y, w), y^{\prime} \leq y, w>0$.
2.3.9. C.6. For any sequence $\mathrm{y}^{\ell}$ such that $\left\|\mathrm{y}^{\ell}\right\| \rightarrow \infty$ as $\ell \rightarrow \infty$ and $\mathrm{w}>0, \mathrm{C}\left(\mathrm{y}^{\ell}, \mathrm{w}\right) \rightarrow \infty$ as $\ell \rightarrow \infty$.
2.3.10. $C .7 . C(y, w)$ is lower semi-continuous in $y$, given $w>0$.

Figure 1. Existence of the Cost Function

2.3.11. C.8. If the graph of the technology (GR) or $T$, is convex, $C(y, w)$ is convex in $y, w>0$.

### 2.4. Discussion of properties of the cost function.

### 2.4.1. C.1.1. Non-negativity: $C(y, w) \geq 0$ for $w>0$.

Because it requires inputs to produce an output and $w$ is positive then $C(y, w)=w x(y, w)>0(y>0)$ where $x(y, w)$ is the optimal level of $x$ for a given $y$.
2.4.2. C.1.2. Nondecreasing in $w$ : If $w \geq w^{\prime}$ then $C(y, w) \geq C\left(y, w^{\prime}\right)$.

Let $\mathrm{w}^{1} \geq \mathrm{w}^{2}$. Let $\mathrm{x}^{1}$ be the cost minimizing input bundle with $\mathrm{w}^{1}$ and $\mathrm{x}^{2}$ be the cost minimizing input bundle with $w^{2}$. Then $w^{2} x^{2} \leq w^{2} x^{1}$ because $x^{1}$ is not cost minimizing with prices $w^{2}$. Now $w^{1} x^{1} \geq w^{2} x^{1}$ because $\mathrm{w}^{1} \geq \mathrm{w}^{2}$ by assumption so that

$$
C\left(w^{1}, y\right)=w^{1} x^{1} \geq w^{2} x^{1} \geq w^{2} x^{2}=C\left(w^{2}, y\right)
$$

2.4.3. C.2. Positively linearly homogenous in w

$$
C(y, \lambda w)=\lambda C(y, w), \quad w>0
$$

Let the cost minimization problem with prices $w$ be given by

$$
\begin{equation*}
C(y, w)=\min _{x}\{w x: x \in V(y)\}, \quad y \in \operatorname{Dom} V, w>0 \tag{4}
\end{equation*}
$$

The $x$ vector that solves this problem will be a function of $y$ and $w$, and is usually denoted $x(y, w)$. The cost function is then given by

$$
\begin{equation*}
C(y, w)=w x(y, w) \tag{5}
\end{equation*}
$$

Now consider the problem with prices $\mathrm{tw}(\mathrm{t}>0)$

$$
\begin{align*}
\hat{C}(y, t w) & =\min _{x}\{t w x: x \epsilon V(y)\}, & & y \in \operatorname{Dom} V, w>0 \\
& =t \min _{x}\{w x: x \in V(y)\}, & & y \in \operatorname{Dom} V, w>0 \tag{6}
\end{align*}
$$

The $x$ vector that solves this problem will be the same as the vector which solves the problem in equation 4 , i.e., $x(y, w)$. The cost function for the revised problem is then given by

$$
\begin{equation*}
\hat{C}(y, t w)=t w x(y, w)=t C(y, w) \tag{7}
\end{equation*}
$$

### 2.4.4. C.3. C is concave and continuous in w

To demonstrate concavity let $(w, x)$ and $\left(w^{\prime}, x^{\prime}\right)$ be two cost-minimizing price-factor combinations and let $w^{\prime \prime}=t w+(1-t) w^{\prime}$ for any $0 \leq t \leq 1$. Concavity implies that $C\left(w^{\prime \prime} y\right) \geq t C(w, y)+(1-t) C\left(w^{\prime}, y\right)$. We can prove this as follows. We have that $C\left(w^{\prime \prime} y\right)=w^{\prime \prime} \cdot x^{\prime \prime}=t w \cdot x^{\prime \prime}+(1-t) w^{\prime} \cdot x^{\prime \prime}$ where $x^{\prime \prime}$ is the optimal choice of $x$ at prices $w^{\prime \prime}$ Because $x^{\prime \prime}$ is not necessarily the cheapest way to produce y at prices $w^{\prime}$ or $w$, we have $w \cdot x^{\prime \prime} \geq$ $C(w, y)$ and $w^{\prime} \cdot x^{\prime \prime} \geq C\left(w^{\prime} y\right)$ so that by substitution $C\left(w^{\prime \prime} y\right) \geq t C(w, y)+(1-t) C\left(w^{\prime}, y\right)$. The point is that if $w$ $\cdot \mathrm{x}^{\prime \prime}$ and $\mathrm{w}^{\prime} \cdot \mathrm{x}^{\prime \prime}$ are each larger than the corresponding term in the linear combination then $\mathrm{C}\left(\mathrm{w}^{\prime \prime}, \mathrm{y}\right)$ is larger than the linear combination. Because $C(y, w)$ is concave it will be continuous by the property of concavity. Rockafellar [14, p. 82] shows that a concave function defined on an open set $(w>0)$ is continuous.

Consider figure 2. Let $\mathrm{x}^{*}$ be the cost minimizing bundle at prices $\mathrm{w}^{*}$. Let the price of $\mathrm{x}_{i}^{*}$ change. At input prices $\left(w^{*}\right)$, costs are at the level $C\left(w^{*}\right)$. If we hold input levels fixed at ( $\mathrm{x}^{*}$ ) and change $\mathrm{w}_{i}$, we move along the tangent line denoted by $\tilde{C}\left(\mathrm{w}_{i}, \bar{w}, \mathrm{y}\right)$, where $\bar{w}^{*}$ and $\bar{x}^{*}$ represent all the prices and inputs other than the ith. Costs are higher along this line than along the cost function because we are not adjusting inputs. Along the cost function, as the price of input increases, we probably use less of input $x_{i}$ and more of other inputs.

### 2.4.5. C.4.1. No fixed costs: $C(0, w)=0, \forall w>0$.

We assume this axiom if the problem is long run, in the short run fixed costs may be positive with zero output. Specifically V.1a implies that to produce zero output, any input vector in $R_{+}^{n}$ will do, including the zero vector with zero costs.
2.4.6. C.4.2. No free lunch: $C(y, w)>0, w>0, y>0$.

Because we cannot produce outputs without inputs (V.1b: no free lunch with the technology), costs for any positive output are positive for strictly positive input prices.

Figure 2. The Cost Function in Concave

2.4.7. C.5. Nondecreasing in $y$ (proportional): $C(\theta y, w) \leq C(y, w), 0 \leq \theta \leq 1, w>0$.

If outputs go down proportionately, costs cannot rise. This is clear because $V\left(y_{1}\right)$ is a subset of $V\left(y_{2}\right)$ if $y_{1} \geq y_{2}$ from V.3, then $C\left(y_{1}, w\right)=\min w x\left|x \in V\left(y_{1}\right) \geq \min w x\right| x \in V\left(y_{2}\right)=C\left(y_{2}, w\right)$. The point is that if we have a smaller set of possible $x^{\prime}$ s to choose from then cost must increase.
2.4.8. C.5.S. Nondecreasing in $y: C\left(y^{\prime}, w\right) \leq C(y, w), y^{\prime} \leq y, w>0$.

If any output goes down, costs cannot increase.
2.4.9. C.6. For any sequence $\mathrm{y}^{\ell}$ such that $\left\|\mathrm{y}^{\ell}\right\| \rightarrow \infty$ as $\ell \rightarrow \infty$ and $\mathrm{w}>0, \mathrm{C}\left(\mathrm{y}^{\ell}, \mathrm{w}\right) \rightarrow \infty$ as $\ell \rightarrow \infty$.

This axiom implies that if outputs increase without bound, so will costs.

### 2.4.10. C.7. $C(y, w)$ is lower semi-continuous in $y$, given $w>0$.

The cost function may not be continuous in output as it is in input prices, but if there are any jump points, it will take the lower value at these points.
2.4.11. C.8. If the graph of the technology $(G R)$ or $T$, is convex, $C(y, w)$ is convex in $y, w>0$.

If the technology is convex (more or less decreasing returns to scale as long as V. 1 holds), costs will rise at an increasing rate as y increases.

### 2.5. Shephard's Lemma.

2.5.1. Definition of Shephard's lemma. In the case where V is strictly quasi-concave and $\mathrm{V}(\mathrm{y})$ is strictly convex the cost minimizing point is unique. Rockafellar [14, p. 242] shows that the cost function is differentiable in $w, w>0$ at $(y, w)$ if and only if the cost minimizing set of inputs at $(y, w)$ is a singleton, i.e., the cost minimizing point is unique. In such cases.

$$
\begin{equation*}
\frac{\partial C(y, w)}{\partial w_{i}}=x_{i}(y, w) \tag{8}
\end{equation*}
$$

which is the Hicksian Demand Curve. As with Hotelling's lemma in the case of the profit function, this lemma allows us to obtain the input demand functions as derivatives of the cost function.
2.5.2. Constructive proof of Shephard's lemma in the case of a single output. For a single output, the cost minimization problem is given by

$$
\begin{equation*}
C(y, w)=\min _{x} w x: f(x)-y=0 \tag{9}
\end{equation*}
$$

The associated Lagrangian is given by

$$
\begin{equation*}
\mathcal{L}=w x-\lambda(f(x)-y) \tag{10}
\end{equation*}
$$

The first order conditions are as follows

$$
\begin{align*}
\frac{\partial \mathcal{L}}{\partial x_{i}} & =w_{i}-\lambda \frac{\partial f}{\partial x_{i}}=0, \quad i=1, \ldots, n  \tag{11a}\\
\frac{\partial \mathcal{L}}{\partial \lambda} & =-(f(x)-y)=0 \tag{11b}
\end{align*}
$$

Solving for the optimal x's yields

$$
\begin{equation*}
x_{i}(y, w) \tag{12}
\end{equation*}
$$

with $C(y, w)$ given by

$$
\begin{equation*}
C(w, y)=w x(y, w) \tag{13}
\end{equation*}
$$

If we now differentiate 13 with respect to $w$ we obtain

$$
\begin{equation*}
\frac{\partial C}{\partial w_{i}}=\Sigma_{j=1}^{n} w_{j} \frac{\partial x_{j}(y, w)}{\partial w_{i}}+x_{i}(y, w) \tag{14}
\end{equation*}
$$

From the first order conditions in equation 11a (assuming that the constraint is satisfied as an equality) we have

$$
\begin{equation*}
w_{j}=\lambda \frac{\partial f}{\partial x_{j}} \tag{15}
\end{equation*}
$$

Substitute the expression for $\mathrm{w}_{j}$ from equation 15 into equation 14 to obtain

$$
\begin{equation*}
\frac{\partial C}{\partial w_{i}}=\Sigma_{j=1}^{n} \lambda \frac{\partial f(x)}{\partial x_{j}} \frac{\partial x_{j}(y, w)}{\partial w_{i}}+x_{i}(y, w) \tag{16}
\end{equation*}
$$

If $\lambda>0$ then equation 11 b implies $(\mathrm{f}(\mathrm{x})-\mathrm{y})=0$. Now differentiate equation 11 b with respect to $\mathrm{w}_{\mathrm{i}}$ to obtain

$$
\begin{equation*}
\Sigma_{j=1}^{n} \frac{\partial f(x(y, w))}{\partial x_{j}} \frac{\partial x_{j}(y, w)}{\partial w_{i}}=0 \tag{17}
\end{equation*}
$$

which implies that the first term in equation 16 is equal to zero and that

$$
\begin{equation*}
\frac{\partial C(y, w)}{\partial w_{i}}=x_{i}(y, w) \tag{18}
\end{equation*}
$$

2.5.3. A Silberberg [17] type proof of Shephard's lemma. Set up a function $L$ as follows

$$
\begin{equation*}
L(y, w, \hat{x})=w \hat{x}-C(w, y) \tag{19}
\end{equation*}
$$

where $\hat{x}$ is the cost minimizing choice of inputs for prices $\hat{w}$. Because $\mathrm{C}(\mathrm{w}, \mathrm{y})$ is the cheapest way to produce $y$ at prices $\mathrm{w}, \mathrm{L} \geq 0$. If $\mathrm{w}=\hat{w}$, then L will be equal to zero. Because this is the minimum value of L , the derivative of L at this point is zero so

$$
\begin{align*}
\frac{\partial L(y, \hat{w}, \hat{x})}{\partial w_{i}} & =\hat{x}_{i}-\frac{\partial C(\hat{w}, y)}{\partial w_{i}}=0  \tag{20}\\
\Rightarrow \hat{x}_{i} & =\frac{\partial C(\hat{w}, y)}{\partial w_{i}}
\end{align*}
$$

The second order necessary conditions for minimizing L imply that

$$
\begin{equation*}
\left[\frac{-\partial^{2} C}{\partial w_{i} \partial w_{j}}\right] \tag{21}
\end{equation*}
$$

is positive semi-definite so that

$$
\begin{equation*}
\frac{\partial^{2} C}{\partial w_{i} \partial w_{j}} \tag{22}
\end{equation*}
$$

is negative semi-definite which implies that $C$ is concave.
2.5.4. Graphical representation of Shephard's lemma. In figure 3 we hold all input prices except the jth fixed at $\hat{w}$. We assume that when the jth price is $\hat{w}_{j}$, the optimal input vector is $\left(\hat{x}_{1}, \hat{x}_{2}, \ldots, \hat{x}_{j}, \ldots, \hat{x}_{n}\right)$. The cost function lies below the tangent line in figure 3 but conincides with the tangent line at $\hat{w}_{j}$ By differentiability the slope of the cost function at this point is the slope of its tangent i.e.,

$$
\begin{equation*}
\frac{\partial C}{\partial w_{j}}=\frac{\partial(\text { tangent })}{\partial w_{j}}=\hat{x}_{j} \tag{23}
\end{equation*}
$$

### 2.6. Sensitivity analysis.

2.6.1. Demand slopes. If the Hessian of the cost function is negative semi-definite, the diagonal elements all must be non-positive(Hadley [11, p. 260-262]) so we have

$$
\begin{equation*}
\frac{\partial^{2} C(y, w)}{\partial w_{i}^{2}}=\frac{\partial x_{i}(y, w)}{\partial w_{i}} \leq 0 \forall_{i} \tag{24}
\end{equation*}
$$

This implies then that Hicksian demand curves slope down because the diagonal elements of the Hessian of the cost function are just the derivatives of input demands with respect to their own prices.

Figure 3. Shephard's Lemma

2.6.2. Cross price effects. By homogeneity of degree zero of input demands and Euler's theorem we have

$$
\begin{equation*}
\Sigma_{j=1}^{n} \frac{\partial x_{i}}{\partial w_{j}} w_{j}=\Sigma_{j \neq i} \frac{\partial x_{i}}{\partial w_{j}} w_{j}+\frac{\partial x_{i}}{\partial w_{i}} w_{i}=0 \tag{25}
\end{equation*}
$$

And we know that

$$
\begin{equation*}
\frac{\partial x_{i}}{\partial w_{i}} \leq 0 \tag{26}
\end{equation*}
$$

by the concavity of C. Therefore

$$
\begin{equation*}
\Sigma_{j \neq i} \frac{\partial x_{i}}{\partial w_{j}} w_{j} \geq 0 \tag{27}
\end{equation*}
$$

This implies that at least one cross price effect is positive.
2.6.3. Symmetry of input demand response to input prices. By Young's theorem

$$
\begin{align*}
\frac{\partial^{2} C}{\partial w_{i} \partial w_{j}} & =\frac{\partial^{2} C}{\partial w_{j} \partial w_{i}}  \tag{28}\\
\Rightarrow \frac{\partial x_{i}}{\partial w_{j}} & =\frac{\partial x_{j}}{\partial w_{i}}
\end{align*}
$$

So cross derivatives in input prices are symmetric.
2.6.4. Marginal cost. Consider the first order conditions for cost minimization. If we differentiate 13 with respect to y we obtain

$$
\begin{equation*}
\frac{\partial C}{\partial y}=\Sigma_{j=1}^{n} w_{j} \frac{\partial x_{j}(y, w)}{\partial y} \tag{29}
\end{equation*}
$$

From the first order conditions in equation 11a (assuming that the constraint is satisfied as an equality) we have

$$
\begin{equation*}
w_{j}=\lambda \frac{\partial f}{\partial x_{j}} \tag{30}
\end{equation*}
$$

Substitute the expression for $\mathrm{w}_{j}$ from equation 30 into equation 29 to obtain

$$
\begin{align*}
\frac{\partial C}{\partial y} & =\Sigma_{j=1}^{n} \lambda \frac{\partial f(x)}{\partial x_{j}} \frac{\partial x_{j}(y, w)}{\partial y} \\
& =\lambda \Sigma_{j=1}^{n} \frac{\partial f(x)}{\partial x_{j}} \frac{\partial x_{j}(y, w)}{\partial y} \tag{31}
\end{align*}
$$

If $\lambda>0$ then equation 11 b implies $(\mathrm{f}(\mathrm{x})-\mathrm{y})=0$. Now differentiate equation 11 b (ignoring $\lambda$ ) with respect to y to obtain

$$
\begin{array}{r}
\Sigma_{j=1}^{n} \frac{\partial f(x(y, w))}{\partial x_{j}} \frac{\partial x_{j}(y, w)}{\partial y}-1=0  \tag{32}\\
\Rightarrow \sum_{j=1}^{n} \frac{\partial f(x(y, w))}{\partial x_{j}} \frac{\partial x_{j}(y, w)}{\partial y}=1
\end{array}
$$

This then implies that the first term in equation 16 that

$$
\begin{equation*}
\frac{\partial C(y, w)}{\partial y}=\lambda(y, w) \tag{33}
\end{equation*}
$$

The Lagrangian multiplier from the cost minimization problem is equal to marginal cost or the increase in cost from increasing the targeted level of y in the constraint.
2.6.5. Symmetry of input demand response to changes in output and changes in marginal cost with respect to input prices. Remember that

$$
\begin{equation*}
\frac{\partial^{2} C}{\partial y \partial w_{i}}=\frac{\partial^{2} C}{\partial w_{i} \partial y} \tag{34}
\end{equation*}
$$

This then implies that

$$
\begin{equation*}
\frac{\partial x_{i}}{\partial y}=\frac{\partial \lambda}{\partial w_{i}} \tag{35}
\end{equation*}
$$

The change in $\mathrm{x}_{\mathrm{i}}(y, w)$ from an increase in $y$ equals the change in marginal cost due to an increase in $\mathrm{w}_{\mathrm{i}}$. 2.6.6. Marginal cost is homogeneous of degree one in input prices. Marginal cost is homogeneous of degree one in input prices.

$$
\begin{equation*}
\frac{\partial C(t y, w)}{\partial y}=t \frac{\partial C(y, w)}{\partial y}, \quad t>0 \tag{36}
\end{equation*}
$$

We can show using the Euler equation. If a function is homogeneous of degree one, then

$$
\begin{equation*}
\Sigma_{i=1}^{n} \frac{\partial f}{\partial x_{i}} x_{i}=f(x) \tag{37}
\end{equation*}
$$

Applying this to marginal cost we obtain

$$
\begin{align*}
\frac{\partial M C(y, w)}{\partial w_{i}} & =\frac{\partial \lambda(y, w)}{\partial w_{i}}=\frac{\partial^{2} C(y, w)}{\partial w_{i} \partial y}=\frac{\partial^{2} C(y, w)}{\partial y \partial w_{i}}=\frac{\partial x_{i}(y, w)}{\partial y} \\
\Rightarrow \Sigma_{i} \frac{\partial \lambda(y, w)}{\partial w_{i}} w_{i} & =\Sigma_{i} \frac{\partial^{2} C(y, w)}{\partial w_{i} \partial y} w_{i}=\Sigma_{i} \frac{\partial^{2} C(y, w)}{\partial y \partial w_{i}} w_{i} \\
& =\frac{\partial}{\partial y}\left(\Sigma_{i} \frac{\partial C(y, w)}{\partial w_{i}} w_{i}\right)  \tag{38}\\
& =\frac{\partial}{\partial y} C(y, w), \quad \text { by homogeneity of } \mathrm{C}(\mathrm{y}, \mathrm{w}) \text { in } \mathrm{w} \\
& =M C(y, w)=\lambda(y, w)
\end{align*}
$$

## 3. Traditional Approach to the Cost Function

3.1. First order conditions for cost minimization. In the case of a single output, the cost function can be obtained by carrying out the maximization problem

$$
\begin{equation*}
C(y, w)=\min _{x} w x: f(x)-y=0 \tag{39}
\end{equation*}
$$

with associated Lagrangian function

$$
\begin{equation*}
\mathcal{L}=w x-\lambda(f(x)-y) \tag{40}
\end{equation*}
$$

The first order conditions are as follows

$$
\begin{array}{cc}
\frac{\partial \mathcal{L}}{\partial x_{1}}=w_{1}- & \lambda \frac{\partial f}{\partial x_{1}}=0 \\
\frac{\partial \mathcal{L}}{\partial x_{2}}=w_{2}- & \lambda \frac{\partial f}{\partial x_{2}}=0 \\
\vdots & \vdots \\
\frac{\partial \mathcal{L}}{\partial x_{n}}=w_{n}- & \lambda \frac{\partial f}{\partial x_{n}}=0 \\
\frac{\partial \lambda}{\partial \lambda}=-(f(x)-y)=0 \tag{41b}
\end{array}
$$

If we take the ratio of any of the first order conditions we obtain

$$
\begin{equation*}
\frac{\frac{\partial f}{\partial x_{j}}}{\frac{\partial f}{\partial x_{i}}}=\frac{w_{j}}{w_{i}} \tag{42}
\end{equation*}
$$

This implies that the RTS between inputs $i$ and $j$ is equal to the negative inverse factor price ratio because

$$
\begin{equation*}
R T S=\frac{\partial x_{i}}{\partial x_{j}}=\frac{-\frac{\partial f}{\partial x_{j}}}{\frac{\partial f}{\partial x_{i}}} \tag{43}
\end{equation*}
$$

Substituting we obtain

$$
\begin{equation*}
R T S=\frac{\partial x_{i}}{\partial x_{j}}=-\frac{w_{j}}{w_{i}} \tag{44}
\end{equation*}
$$

Graphically this implies that the slope of an isocost line is equal to the slope of the lower boundary of $\mathrm{V}(\mathrm{y})$. Note that an isocost line is given by

$$
\begin{align*}
\overline{\operatorname{cost}} & =w_{1} x_{1}+w_{2} x_{2}+\ldots+w_{n} x_{n} \\
\Rightarrow w_{i} x_{i} & =\overline{\operatorname{cost}}-w_{1} x_{1}-w_{2} x_{2}-\ldots-w_{i-1} x_{i-1}-w_{i+1} x_{i+1}-\ldots-w_{j} x_{j}-\ldots-w_{n} x_{n} \\
\Rightarrow x_{j} & =\frac{\overline{\operatorname{cost}}}{w_{i}}-\frac{w_{1}}{w_{i}} x_{1}-\frac{w_{2}}{w_{i}} x_{2}-\ldots-\frac{w_{i-1}}{w_{i}} x_{i-1}-\frac{w_{i+1}}{w_{i}} x_{i+1}-\ldots-\frac{w_{j}}{w_{i}} x_{j}-\ldots-\frac{w_{n}}{w_{i}} x_{n} \\
\Rightarrow \text { Slope of isocost } & =-\frac{w_{j}}{w_{i}} \tag{45}
\end{align*}
$$

In figure 4, we can see that slope of the isocost line is tangent to the the slope of the lower boundary of $\mathrm{V}(\mathrm{y})$ at the cost minmimizing point.

Figure 4. Cost Minimizing Input Combination

In figure 5, we can see that slope of the isocost line is tangent to the the slope of the lower boundary of $\mathrm{V}(\mathrm{y})$ at different levels of output.

Figure 5. Cost Minimizing Input Combinations at Alternative Output Levels

### 3.2. Notes on quasiconcavity.

Definition 1. A real valued function $f$, defined on a convex set $X \subset \Re^{n}$, a said to be quasiconcave if

$$
\begin{equation*}
f\left(\lambda x^{1}++(1-\lambda) x^{2}\right) \geq \min \left[f\left(x^{1}\right), f\left(x^{2}\right)\right] \tag{46}
\end{equation*}
$$

A function f is said to be quasiconvex if -f is quasiconcave.

Theorem 1. Let $f$ be a real valued function defined on a convex set $X \subset R^{n}$. The upper contour sets $\{(x, y): x \in S, \alpha$ $\leq f(x)\}$ of fare convex for every $\alpha \in R$ if and only iff is a quasiconcave function.

Proof. Suppose that $\mathrm{S}(\mathrm{f}, \alpha)$ is a convex set for every $\alpha \in \mathrm{R}$ and let $\mathrm{x}^{1} \in \mathrm{X}, \mathrm{x}^{2} \in \mathrm{X}, \bar{\alpha}=\min \left[\mathrm{f}\left(\mathrm{x}^{1}\right), \mathrm{f}\left(\mathrm{x}^{2}\right)\right]$. Then $x^{1} \in S(f, \bar{\alpha})$ and $x^{2} \in S(f, \bar{\alpha})$, and because $S(f, \bar{\alpha})$ is convex, $\left(\lambda x^{1}+(1-\lambda) x^{2}\right) \in S(f, \bar{\alpha})$ for arbitrary $\lambda$. Hence

$$
\begin{equation*}
f\left(\lambda x^{1}+(1-\lambda) x^{2}\right) \geq \bar{\alpha}=\min \left[f\left(x^{1}\right), f\left(x^{2}\right)\right] \tag{47}
\end{equation*}
$$

Conversely, let $\mathrm{S}(\mathrm{f}, \alpha)$ be any level set of f . Let $\mathrm{x}^{1} \in \mathrm{~S}(\mathrm{f}, \alpha)$ and $\mathrm{x}^{2} \in \mathrm{~S}(\mathrm{f}, \alpha)$. Then

$$
\begin{equation*}
f\left(x^{1}\right) \geq \alpha, \quad f\left(x^{2}\right) \geq \alpha \tag{48}
\end{equation*}
$$

and because f is quasiconcave, we have

$$
\begin{equation*}
f\left(\lambda x^{1}+(1-\lambda) x^{2}\right) \geq \alpha \tag{49}
\end{equation*}
$$

and $\left(\lambda x^{1}+(1-\lambda) x^{2}\right) \in S(f, \alpha)$.

Theorem 2. Let $f$ be differentiable on an open convex set $X \subset R^{n}$. Then $f$ is quasiconcave if and only if for any $x^{1} \in$ $X, x^{2} \in X$ such that

$$
\begin{equation*}
f\left(x^{1}\right) \geq f\left(x^{2}\right) \tag{50}
\end{equation*}
$$

we have

$$
\begin{equation*}
\left(x^{1}-x^{2}\right)^{\prime} \nabla f\left(x^{2}\right) \geq 0 \tag{51}
\end{equation*}
$$

Definition 2. The kth-ordered bordered determinant $\mathrm{D}_{k}(\mathrm{f}, \mathrm{x})$ of a twice differentiable function f at at point $x \in \mathrm{R}^{n}$ is defined as

$$
D_{k}(f, x)=\operatorname{det}\left[\begin{array}{ccccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{1} \partial x_{k}} & \frac{\partial f}{\partial x_{1}}  \tag{52}\\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{2} \partial x_{k}} & \frac{\partial f}{\partial x_{2}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{\partial^{2} f}{\partial x_{k} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{k} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{k}^{2}} & \frac{\partial f}{\partial x_{k}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & \cdots & \frac{\partial f}{\partial x_{k}} & 0
\end{array}\right] \quad k=1,2, \ldots, n
$$

Definition 3. Some authors define the kth-ordered bordered determinant $D_{k}(f, x)$ of a twice differentiable function $f$ at at point $x \in R^{n}$ in a different fashion where the first derivatives of the function $f$ border the Hessian of the function on the top and left as compared to in the bottom and right as in equation 52.

$$
D_{k}(f, x)=\operatorname{det}\left[\begin{array}{ccccc}
0 & \frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & \cdots & \frac{\partial f}{\partial x_{k}}  \tag{53}\\
\frac{\partial f}{\partial x_{1}} & \frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{1} \partial x_{k}} \\
\frac{\partial f}{\partial x_{2}} & \frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{2} \partial x_{k}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{\partial f}{\partial x_{k}} & \frac{\partial^{2} f}{\partial x_{k} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{k} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{k}^{2}}
\end{array}\right] k=1,2, \ldots, n
$$

The determinant in equation 52 and the determinant in equation 53 will be the same. If we interchange any two rows or any two columns of a determinant, the determinant will change sign but keep its absolute
value. A certain number of row exchanges will be necessary to move the bottom row to the top. A like number of column exchanges will be necessary to move the rightmost column to the left. Given that equations 52 and 53 are the same except for this even number of row and column exchanges, the determinants will be the same. You can illustrate this to yourself using the following three variable example.
3.2.1. Quasi-concavity and bordered hessians.
a.: If $f(x)$ is quasi-concave on a solid (non-empty interior) convex set $X \subset R^{n}$, then

$$
\begin{equation*}
(-1)^{k} D_{k}(f, x) \geq 0, \quad k=1,2, \ldots, n \tag{54}
\end{equation*}
$$

for every $\mathrm{x} \in \mathrm{X}$.
b.: If

$$
\begin{equation*}
(-1)^{k} D_{k}(f, x)>0, \quad k=1,2, \ldots, n \tag{55}
\end{equation*}
$$

for every $\mathrm{x} \in \mathrm{X}$,then $\mathrm{f}(\mathrm{x})$ is quasi-concave on X (Avriel [3, p.149], Arrow and Enthoven [2, p. 781-782]
If f is quasiconcave, then when k is odd, $\mathrm{D}_{k}(\mathrm{f}, \mathrm{x})$ will be negative and when k is even, $\mathrm{D}_{k}(\mathrm{f}, \mathrm{x})$ will be positive. Thus $\mathrm{D}_{k}(\mathrm{f}, \mathrm{x})$ will alternate in sign beginning with positive in the case of two variables.
3.2.2. Relationship of quasi-concavity to signs of minors (cofactors) of a matrix. Let

$$
F=\left|\begin{array}{ccccc}
0 & \frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & \cdots & \frac{\partial f}{\partial x_{n}}  \tag{56}\\
\frac{\partial f}{\partial x_{1}} & \frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{\partial j} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x^{2} \partial x_{n}} \\
\frac{\partial f}{\partial x_{2}} & \frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{2} \partial x_{n}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{\partial f}{\partial x_{n}} & \frac{\partial^{2} f}{\partial x_{n} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{n} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{n}^{2}}
\end{array}\right|=\operatorname{det} H_{B}
$$

where $\operatorname{det} \mathrm{H}_{B}$ is the determinant of the bordered Hessian of the function f . Now let $\mathrm{F}_{i j}$ be the cofactor of $\frac{\partial^{2} f}{\partial x_{i} \partial x_{j}}$ in the matrix $\mathrm{H}_{B}$. It is clear that $\mathrm{F}_{n n}$ and F have opposite signs because F includes the last row and column of $\mathrm{H}_{B}$ and $\mathrm{F}_{n n}$ does not. If the $(-1)^{n}$ in front of the cofactors is positive then $\mathrm{F}_{n n}$ must be positive with F negative and vice versa. Since the ordering of rows since is arbitrary it is also clear that $\mathrm{F}_{i i}$ and F have opposite signs. Thus when a function is quasi-concave $\frac{F_{i i}}{F}$ will have a negative sign.

### 3.3. Second order conditions for cost minimization.

3.3.1. Note on requirements for a minimum of a constrained problem. Consider a general constrained optimization problem with one constraint.

$$
\begin{gathered}
\underset{x}{\operatorname{maximize}} f(x) \\
\text { subject to } g(x)=0
\end{gathered}
$$

where $g(x)=0$ denotes a constraint, We can also write this as

$$
\max _{x_{1}, x_{2}, \ldots x_{n}} f\left(x_{1}, x_{2}, \ldots, x_{n}\right)
$$

subject to

$$
\begin{equation*}
g\left(x_{1}, x_{2}, \ldots, x_{n}\right)=0 \tag{57}
\end{equation*}
$$

The solution can be obtained using the Lagrangian function

$$
\begin{equation*}
\mathcal{L}(x ; \lambda)=f\left(x_{1}, x_{2}, \ldots\right)-\lambda g(x) \tag{58}
\end{equation*}
$$

Notice that the gradient of $\mathcal{L}$ will involve a set of derivatives, i.e.

$$
\nabla_{x} \mathcal{L}=\nabla_{x} f(x)-\lambda \nabla_{x} g(x)
$$

There will be one equation for each $x$. There will also an equation involving the derivative of $\mathcal{L}$ with respect to $\lambda$. The necessary conditions for an extremum of $f$ with the equality constraints $g(x)=0$ are that

$$
\begin{equation*}
\nabla \mathcal{L}\left(x^{*}, \lambda^{*}\right)=0 \tag{59}
\end{equation*}
$$

where it is implicit that the gradient in (59) is with respect to both $x$ and $\lambda$. The typical sufficient conditions for a maximum or minimum of $f\left(x_{1}, x_{2}, \ldots, x_{n}\right)$ subject to $g\left(x_{1}, x_{2}, \ldots, x_{n}\right)=0$ require that $f$ and $g$ be twice continuously differentiable real-valued functions on $\mathrm{R}^{n}$. Then if there exist vectors $\mathrm{x}^{*} \in \mathrm{R}^{n}$, and $\lambda^{*} \in R^{1}$ such that

$$
\begin{equation*}
\nabla \mathcal{L}\left(x^{*}, \lambda^{*}\right)=0 \tag{60}
\end{equation*}
$$

and for every non-zero vector $z \in R^{n}$ satisfying

$$
\begin{equation*}
z^{\prime} \nabla g\left(x^{*}\right)=0 \tag{61}
\end{equation*}
$$

it follows that

$$
\begin{equation*}
z^{\prime} \nabla_{x}^{2} \mathcal{L}\left(x^{*}, \lambda^{*}\right) z>0 \tag{62}
\end{equation*}
$$

then $f$ has a strict local minimum at $x^{*}$, subject to $g(x)=0$. If the inequality in (62) is reversed, then $f$ has strict local maximum at $x^{*}$.

For the cost minimization problem the Lagrangian is given by

$$
\begin{equation*}
\mathcal{L}=w x-\lambda(f(x)-y) \tag{63}
\end{equation*}
$$

where the objective function is $w x$ and the constraint is $f(x)-y=0$. Differentiating equation 63 twice with respect to $x$ we obtain

$$
\begin{align*}
\nabla_{x}^{2} \mathcal{L}\left(x^{*}, \lambda^{*}\right) & =\left[-\lambda \frac{\partial^{2} f(x)}{\partial x_{i} \partial x_{j}}\right] \\
& =-\lambda\left[\frac{\partial^{2} f(x)}{\partial x_{i} \partial x_{j}}\right] \tag{64}
\end{align*}
$$

And so the condition in equation 62 will imply that

$$
\begin{align*}
& -\lambda z^{\prime}\left[\frac{\partial^{2} f(x)}{\partial x_{i} \partial x_{j}}\right] z>0  \tag{65}\\
& \Rightarrow z^{\prime}\left[\frac{\partial^{2} f(x)}{\partial x_{i} \partial x_{j}}\right] z<0
\end{align*}
$$

for all z satisfying $\mathrm{z}^{\prime} \nabla \mathrm{f}(\mathrm{x})=0$. This is also the condition for f to be a quasi-concave function. (Avriel [3, p.149]. Thus these sufficient conditions imply that f must be quasi-concave.
3.3.2. Checking the sufficient conditions for cost minimization. Consider the general constrained minimization problem where f and g are twice continuously differentiable real valued functions. If there exist vectors $x^{*} \in R^{n}, \lambda^{*} \in R^{m}$, such that

$$
\begin{equation*}
\nabla L\left(x^{*}, \lambda^{*}\right)=0 \tag{66}
\end{equation*}
$$

and if

$$
D(p)=(-1) \operatorname{det}\left[\begin{array}{cccc}
\frac{\partial^{2} L\left(x^{*}, \lambda^{*}\right)}{\partial x_{1} \partial x_{1}} & \cdots & \frac{\partial^{2} L\left(x^{*}, \lambda^{*}\right)}{\partial x_{1} \partial x_{p}} & \frac{\partial g\left(x^{*}\right)}{\partial x_{1}}  \tag{67}\\
\cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot \\
\frac{\partial^{2} L\left(x^{*}, \lambda^{*}\right)}{\partial x_{p} \partial x_{1}} & \ldots & \frac{\partial^{2} L\left(x^{*}, \lambda^{*}\right)}{\partial x_{p} \partial x_{p}} & \frac{\partial g\left(x^{*}\right)}{\partial x_{p}} \\
\frac{\partial g\left(x^{*}\right)}{\partial x_{1}} & \cdots & \frac{\partial g\left(x^{*}\right)}{\partial x_{p}} & 0
\end{array}\right]>0
$$

for $p=2,3, \ldots, n$, then $f$ has a strict local minimum at $x^{*}$, such that

$$
\begin{equation*}
g\left(x^{*}\right)=0 \tag{68}
\end{equation*}
$$

We can also write this as follows where after multiplying both sides by negative one.

$$
D(p)=\operatorname{det}\left[\begin{array}{cccc}
\frac{\partial^{2} L\left(x^{*}, \lambda^{*}\right)}{\partial x_{1} \partial x_{1}} & \ldots & \frac{\partial^{2} L\left(x^{*}, \lambda^{*}\right)}{\partial x_{1} \partial x_{p}} & \frac{\partial g\left(x^{*}\right)}{\partial x_{1}}  \tag{69}\\
\cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot \\
\frac{\partial^{2} L\left(x^{*}, \lambda^{*}\right)}{\partial x_{p} \partial x_{1}} & \ldots & \frac{\partial^{2} L\left(x^{*}, \lambda^{*}\right)}{\partial x_{p} \partial x_{p}} & \frac{\partial g\left(x^{*}\right)}{\partial x_{p}} \\
\frac{\partial g\left(x^{*}\right)}{\partial x_{1}} & \ldots & \frac{\partial g\left(x^{*}\right)}{\partial x_{p}} & 0
\end{array}\right]<0
$$

for $p=2,3, \ldots, n$, then $f$ has a strict local minimum at $x^{*}$, such that

$$
\begin{equation*}
g\left(x^{*}\right)=0 \tag{70}
\end{equation*}
$$

We check the determinants in (69) starting with the one that has 2 elements in each row and column of the Hessian and 1 element in each row or column of the derivative of the constraint with respect to $x$.

For the cost minimization problem, $D(p)$ is given by

$$
D(p)=\left|\begin{array}{ccccc}
\frac{-\lambda \partial^{2} f}{\partial x^{2}} & \frac{-\lambda \partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{-\lambda \partial^{2} f}{\partial x_{1} \partial x_{p}} & \frac{\partial f}{\partial x_{1}}  \tag{71}\\
\frac{-\lambda \partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{-\lambda \partial^{2} f}{\partial x_{2}^{2}} & \cdots & \frac{-\lambda \partial^{2} f}{\partial x_{2} \partial x_{p}} & \frac{\partial f}{\partial x_{2}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{-\lambda \partial^{2} f}{\partial x_{p} \partial x_{1}} & \frac{-\lambda \partial^{2} f}{\partial x_{p} \partial x_{2}} & \cdots & \frac{-\lambda \partial^{2} f}{\partial x_{p}^{2}} & \frac{\partial f}{\partial x_{p}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & \cdots & \frac{\partial f}{\partial x_{p}} & 0
\end{array}\right|
$$

In order to factor $-\lambda$ out of the determinant and write the second order conditions in terms of the bordered Hessian of the production function multiply last row and last column of $\mathrm{D}(\mathrm{p})$ by $-\lambda$, multiply out front by $\left(\frac{-1}{\lambda}\right)^{2}$, and then compute the determinant.

$$
D(p)=\left(-\frac{1}{\lambda}\right)^{2}\left|\begin{array}{ccccc}
\frac{-\lambda \partial^{2} f}{\partial x_{1}^{2}} & \frac{-\lambda \partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{-\lambda \partial^{2} f}{\partial x_{1} \partial x_{p}} & -\lambda \frac{\partial f}{\partial x_{1}}  \tag{72}\\
\frac{-\lambda \partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{-\lambda \partial^{2} f}{\partial x_{2}^{2}} & \cdots & \frac{-\lambda \partial^{2} f}{\partial x_{2} \partial x_{p}} & -\lambda \frac{\partial f}{\partial x_{2}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{-\lambda \lambda^{2} f}{\partial x_{p} \partial x_{1}} & \frac{-\lambda \partial^{2} f}{\partial x_{p} \partial x_{2}} & \cdots & \frac{-\lambda \partial^{2} f}{\partial x_{2}^{2}} & -\lambda \frac{\partial f}{\partial x_{p}} \\
-\lambda \frac{\partial f}{\partial x_{1}} & -\lambda \frac{\partial f}{\partial x_{2}} & \cdots & -\lambda \frac{\partial f}{\partial x_{p}} & 0
\end{array}\right|
$$

Now factor $-\lambda$ out of all $\mathrm{p}+1$ rows of $\mathrm{D}(\mathrm{p})$.

$$
D(p)=(-\lambda)^{p+1}\left(-\frac{1}{\lambda}\right)^{2}\left|\begin{array}{ccccc}
\frac{\partial^{2} f}{\partial x_{1}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{1} \partial x_{p}} & \frac{\partial f}{\partial x_{1}}  \tag{73}\\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{\prime} f}{\partial x_{2}^{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{2} \partial x_{p}} & \frac{\partial f}{\partial x_{2}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{\partial^{2} f}{\partial x_{p} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{p} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{p}^{2}} & \frac{\partial f}{\partial x_{p}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & \cdots & \frac{\partial f}{\partial x_{p}} & 0
\end{array}\right|
$$

Because $f(x)$ must be greater than or equal to $y$ in the cost minimization problem, we can assume $\lambda>0$ so that the sign of the $D(p)$ in equation 73 is equal to the sign of

$$
(-1)^{p+1}\left|\begin{array}{ccccc}
\frac{\partial^{2} f}{\partial x^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{1} \partial x_{p}} & \frac{\partial f}{\partial x_{1}}  \tag{74}\\
\frac{x^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{2} \partial x_{p}} & \frac{\partial f}{\partial x_{2}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{\partial^{2} f}{\partial x_{p} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{p} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{p}^{2}} & \frac{\partial f}{\partial x_{p}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & \cdots & \frac{\partial f}{\partial x_{p}} & 0
\end{array}\right|
$$

For a minimum we want $|\mathrm{D}|<0$ for $\mathrm{p}=2, \ldots, \mathrm{n}$. Therefore for a minimum, a sufficient condition is that

$$
(-1)^{p+1}\left|\begin{array}{ccccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{1} \partial x_{p}} & \frac{\partial f}{\partial x_{1}}  \tag{75}\\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{2} \partial x_{p}} & \frac{\partial f}{\partial x_{2}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{\partial^{2} f}{\partial x_{p} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{p} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{p}^{2}} & \frac{\partial f}{\partial x_{p}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & \cdots & \frac{\partial f}{\partial x_{p}} & 0
\end{array}\right|<0
$$

or

$$
(-1)^{p}\left|\begin{array}{ccccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{1} \partial x_{p}} & \frac{\partial f}{\partial x_{1}}  \tag{76}\\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{2} \partial x_{p}} & \frac{\partial f}{\partial x_{2}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{\partial^{2} f}{\partial x_{p} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{p} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{p}^{2}} & \frac{\partial f}{\partial x_{p}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & \cdots & \frac{\partial f}{\partial x_{p}} & 0
\end{array}\right|>0
$$

This condition in equation 76 is the condition for the quasi-concavity of the production function f from equation 55. (Avriel [3, p. 149].
3.3.3. Example problem with two variable inputs. The Lagrangian function is given by

$$
\begin{equation*}
\mathcal{L}=w_{1} x_{1}+w_{2} x_{2}-\lambda\left(f\left(x_{1}, x_{2}\right)-y\right) \tag{77}
\end{equation*}
$$

The first order conditions are as follows

$$
\begin{align*}
\frac{\partial \mathcal{L}}{\partial x_{1}} & =w_{1}-\lambda \frac{\partial f}{\partial x_{1}}=0  \tag{78a}\\
\frac{\partial \mathcal{L}}{\partial x_{2}} & =w_{2}-\lambda \frac{\partial f}{\partial x_{2}}=0  \tag{78b}\\
& -\lambda(f(x)-y)=0 \tag{78c}
\end{align*}
$$

The bordered Hessian for the Lagrangian is given by

$$
\begin{align*}
H_{B} & =\left[\begin{array}{ccc}
\frac{\partial^{2} \mathcal{L}\left(x^{*}, \lambda^{*}\right)}{\partial x_{1} \partial x_{1}} & \frac{\partial^{2} \mathcal{L}\left(x^{*}, \lambda^{*}\right)}{\partial x_{1} \partial x_{2}} & \frac{\partial g\left(x^{*}\right)}{\partial x_{1}} \\
\frac{\partial^{2} \mathcal{L}\left(x^{*}, \lambda^{*}\right)}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} \mathcal{L}\left(x^{*}, \lambda^{*}\right)}{\partial x_{2} \partial x_{2}} & \frac{\partial g\left(x^{*}\right)}{\partial x_{2}} \\
\frac{\partial g\left(x^{*}\right)}{\partial x_{1}} & \frac{\partial g\left(x^{*}\right)}{\partial x_{2}} & 0
\end{array}\right]  \tag{79}\\
& =\left[\begin{array}{ccc}
\frac{-\lambda \partial^{2} f}{\partial x_{1}^{2}} & \frac{-\lambda \partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}} \\
\frac{-\lambda \lambda^{2} f}{\partial x_{2} \partial x_{1}} & \frac{-\lambda \partial^{2} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & 0
\end{array}\right]
\end{align*}
$$

The determinant of this matrix must be negative for this solution to be a minimum. To see how this relates to the bordered Hessian of the production function multiply the last row and column by $-\lambda$ and the whole determinant by $\left(\frac{-1}{\lambda}\right)^{2}$ as follows

$$
\left[\begin{array}{ccc}
\frac{-\lambda \partial^{2} f}{\partial x_{1}^{2}} & \frac{-\lambda \partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}}  \tag{80}\\
\frac{-\lambda \partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{-\lambda \partial^{2} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & 0
\end{array}\right]=\left(\frac{-1}{\lambda}\right)^{2}\left|\begin{array}{ccc}
\frac{-\lambda \partial^{2} f}{\partial x_{1}^{2}} & \frac{-\lambda \partial^{2} f}{\partial x_{1} \partial x_{2}} & -\lambda \frac{\partial f}{\partial x_{1}} \\
\frac{-\lambda \partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{-\lambda \partial^{2} f}{\partial x_{2}^{2}} & -\lambda \frac{\partial f}{\partial x_{2}} \\
-\lambda \frac{\partial f}{\partial x_{1}} & -\lambda \frac{\partial f}{\partial x_{2}} & 0
\end{array}\right|=(-\lambda)^{3}\left(\frac{-1}{\lambda}\right)^{2}\left|\begin{array}{ccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}} \\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & 0
\end{array}\right|
$$

With $\lambda>0$ this gives

$$
(-1)^{3}\left|\begin{array}{ccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}}  \tag{81}\\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & 0
\end{array}\right|
$$

so that

$$
\left|\begin{array}{ccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}}  \tag{82}\\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & 0
\end{array}\right|>0
$$

for a minimum. This is the condition for a quasi-concave function with two variables. If there were three variables, the determinant of the next bordered Hessian would be negative.
3.4. Input demands. If we solve the equations in 41 for $x_{j}, j=1,2, \ldots, n$, and $\lambda$, we obtain the optimal values of $x$ for a given $y$ and $w$. As a function of $w$ for a fixed $y$, this gives the vector of factor demands for $x$ and the optimal Lagrangian multiplier $\lambda(y, w)$.

$$
\begin{align*}
& \tilde{x}=\tilde{x}(y, w)=\left(\tilde{x}_{1}(y, w), \tilde{x}_{2}(y, w), \ldots, \tilde{x}_{n}(y, w)\right) \\
& \tilde{\lambda}=\tilde{\lambda}(y, w) \tag{83}
\end{align*}
$$

3.5. Sensitivity analysis. We can investigate the properties of $\tilde{x}(\mathrm{y}, \mathrm{w})$ by substituting $\tilde{x}(\mathrm{y}, \mathrm{w})$ for x in equation 41 and then treating it as an identity.

$$
\begin{align*}
& \frac{\partial \mathcal{L}}{\partial x_{1}}=w_{1}-\quad \lambda \frac{\partial f\left(\tilde{x}_{1}(y, w), \tilde{x}_{2}(y, w), \ldots, \tilde{x}_{n}(y, w)\right)}{\partial x_{1}}=0 \\
& \frac{\partial \mathcal{L}}{\partial x_{2}}=w_{2}-\quad \lambda \frac{\partial f\left(\tilde{x}_{1}(y, w), \tilde{x}_{2}(y, w), \ldots, \tilde{x}_{n}(y, w)\right)}{\partial x_{2}}=0  \tag{84a}\\
& \vdots \\
& \frac{\partial \mathcal{L}}{\partial x_{n}}=w_{n}-\quad \lambda \frac{\partial f\left(\tilde{x}_{1}(y, w), \tilde{x}_{2}(y, w), \ldots, \tilde{x}_{n}(y, w)\right)}{\partial x_{n}}=0 \\
&  \tag{84b}\\
& \\
& \\
& \\
& \\
& \\
& \\
& \\
& \\
& \\
& \\
& \\
& \\
&\left(\left(\tilde{x}_{1}(y, w), \tilde{x}_{2}(y, w), \ldots, \tilde{x}_{n}(y, w)\right)-y\right)=0
\end{align*}
$$

Where it is obvious we write $\mathrm{x}(\mathrm{y}, \mathrm{w})$ for $\tilde{x}(\mathrm{y}, \mathrm{w})$ and $\mathrm{x}_{j}(\mathrm{y}, \mathrm{w})$ for $\tilde{x}_{j}(\mathrm{y}, \mathrm{w})$. If we differentiate the first equation in 84 a with respect to $\mathrm{w}_{j}$ we obtain

$$
\left.\begin{array}{r}
0-\lambda\left(\frac{\partial^{2} f(x(y, w))}{\partial x_{1}^{2}} \frac{\partial x_{1}(y, w)}{\partial w_{j}}+\frac{\partial^{2} f(x(y, w))}{\partial x_{2} \partial x_{1}} \frac{\partial x_{2}(y, w)}{\partial w_{j}}+\frac{\partial^{2} f(x(y, w))}{\partial x_{3} \partial x_{1}} \frac{\partial x_{3}(y, w)}{\partial w_{j}}+\cdots\right)-\frac{\partial f(x(y, w))}{\partial x_{1}} \frac{\partial \lambda(y, w)}{\partial w_{j}} \equiv 0 \\
\Rightarrow \lambda\left(\frac{\partial^{2} f(x(y, w))}{\partial x_{1}^{2}}\right.
\end{array} \frac{\partial^{2} f(x(y, w))}{\partial x_{2} \partial x_{1}} \quad \frac{\partial^{2} f(x(y, w))}{\partial x_{3} \partial x_{1}} \cdots \frac{\partial^{2} f(x(y, w))}{\partial x_{n} \partial x_{1}} \quad \frac{\partial f(x(y, w))}{\partial x_{1}}\right)\left(\begin{array}{c}
\frac{\partial x_{1}(y, w)}{\partial w_{j}} \\
\frac{\partial x_{2}(y, w)}{\partial w_{j}}  \tag{85}\\
\frac{\partial x_{3}(y, w)}{\partial w_{j}} \\
\vdots \\
\frac{\partial x_{n}(y, w)}{\partial w_{j}} \\
\frac{1}{\lambda} \frac{\partial \lambda(y, w)}{\partial w_{j}}
\end{array}\right) \equiv 0
$$

If we differentiate the second equation in 84 a with respect to $\mathrm{w}_{j}$ we obtain
$0-\lambda\left(\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{2}} \frac{\partial x_{1}(p, w)}{\partial w_{j}}+\frac{\partial^{2} f(x(y, w))}{\partial x_{2}^{2}} \frac{\partial x_{2}(y, w)}{\partial w_{j}}+\frac{\partial^{2} f(x(y, w))}{\partial x_{3} \partial x_{2}} \frac{\partial x_{3}(y, w)}{\partial w_{j}}+\cdots\right)-\frac{\partial f(x(y, w))}{\partial x_{2}} \frac{\partial \lambda(y, w)}{\partial w_{j}} \equiv 0$

$$
\Rightarrow \lambda\left(\begin{array}{lllll}
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{2}} & \frac{\partial^{2} f(x(y, w))}{\partial x_{2}^{2}} & \frac{\partial^{2} f(x(y, w))}{\partial x_{3} \partial x_{2}} \cdots \frac{\partial^{2} f(x(y, w))}{\partial x_{n} \partial x_{2}} & \frac{\partial f(x(y, w))}{\partial x_{2}}
\end{array}\right)\left(\begin{array}{c}
\frac{\partial x_{1}(y, w)}{\partial w_{j}} \\
\frac{\partial x_{2}(y, w)}{\partial w_{j}}  \tag{86}\\
\frac{\partial x_{3}(y, w)}{\partial w_{j}} \\
\vdots \\
\frac{\partial x_{n}(y, w)}{\partial w_{j}} \\
\frac{\partial \partial(y, w)}{\lambda} \frac{\partial w_{j}}{\partial w_{j}}
\end{array}\right) \equiv 0
$$

If we differentiate the jth equation in 84 a with respect to $\mathrm{w}_{j}$ we obtain

$$
\begin{array}{r}
1-\lambda\left(\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{j}} \frac{\partial x_{1}(y, w)}{\partial w_{j}}+\frac{\partial^{2} f(x(y, w))}{\partial x_{2} \partial x_{j}} \frac{\partial x_{2}(y, w)}{\partial w_{j}}+\cdots+\frac{\partial^{2} f(x(y, w))}{\partial x_{j}^{2}} \frac{\partial x_{j}(y, w)}{\partial w_{j}}+\cdots\right)-\frac{\partial f(x(y, w))}{\partial x_{j}} \frac{\partial \lambda(y, w)}{\partial w_{j}} \equiv 0 \\
\Rightarrow \lambda\left(\begin{array}{lllll}
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{j}} & \frac{\partial^{2} f(x(y, w))}{\partial x_{2} \partial x_{j}} & \cdots & \frac{\partial^{2} f(x(y, w))}{\partial x_{j}^{2}} \cdots \frac{\partial^{2} f(x(y, w)}{\partial x_{n} \partial x_{j}} & \frac{\partial f(x(y, w))}{\partial x_{j}}
\end{array}\right)\left(\begin{array}{c}
\frac{\partial x_{1}(y, w)}{\partial w_{j}} \\
\frac{\partial x_{2}(y, w)}{\partial w_{j}} \\
\frac{\partial x_{3}(y, w)}{\partial w_{j}} \\
\vdots \\
\frac{\partial x_{n}(y, w)}{\partial w_{j}} \\
\frac{1}{\lambda} \frac{\partial \lambda(y, w)}{\partial w_{j}}
\end{array}\right) \equiv 1 \tag{87}
\end{array}
$$

Continuing in the same fashion we obtain

$$
\lambda\left(\begin{array}{ccccccc}
\frac{\partial^{2} f(x(y, w))}{\partial x_{1}^{2}} & \frac{\partial^{2} f(x(y, w)}{\partial x_{2} \partial x_{1}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{j} \partial x_{1}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n} \partial x_{1}} & \frac{\partial f(x(y, w)}{\partial x_{1}}  \tag{88}\\
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{2}} & \frac{\partial^{2} f(x(y, w)}{\partial x_{2}^{2}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{j} \partial x_{2}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n} \partial x_{2}} & \frac{\partial f(x(y, w)}{\partial x_{2}} \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \\
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{j}} & \frac{\partial^{2} f(x(y, w)}{\partial x_{2} \partial x_{j}} & \ldots & \frac{\partial^{2} f(x(y, w)}{\partial x_{j}^{2}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n} \partial x_{j}} & \frac{\partial f(x(y, w)}{\partial x_{j}} \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \\
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{n}} & \frac{\partial^{2} f(x(y, w)}{\partial x_{2} \partial x_{n}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{j} \partial x_{n}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n}^{2}} & \frac{\partial f(x(y, w)}{\partial x_{n}}
\end{array}\right)\left(\begin{array}{c}
\frac{\partial x_{1}(y, w)}{\partial w_{j}} \\
\frac{\partial x_{2}(y, w)}{\partial w_{j}} \\
\vdots \\
\frac{\partial x_{j}(y, w)}{\partial w_{j}} \\
\vdots \\
\frac{\partial x_{n}(y, w)}{\partial w_{j}} \\
\frac{1}{\lambda} \frac{\partial \lambda(y, w)}{\partial w_{j}}
\end{array}\right) \equiv\left(\begin{array}{c}
0 \\
0 \\
\vdots \\
1 \\
\vdots \\
0
\end{array}\right)
$$

This is a system of n equations in $\mathrm{n}+1$ unknowns. Equation 84 b implies that $-\lambda(\mathrm{y}, \mathrm{w})\left(f\left(\left(\tilde{x}_{1}(y, w), \tilde{x}_{2}(y, w), \ldots, \tilde{x}_{n}(y, w)\right)\right.\right.$ If we differentiate equation 84 b with respect to $\mathrm{w}_{j}$ we obtain

$$
\begin{align*}
-\lambda & \left(\frac{\partial f(x(y, w))}{\partial x_{1}} \frac{\partial x_{1}(y, w)}{\partial w_{j}}+\frac{\partial f(x(y, w)}{\partial x_{2}} \frac{\partial x_{2}(y, w)}{\partial w_{j}}+\cdots+\frac{\partial f(x(y, w)}{\partial x_{j}} \frac{\partial x_{j}(y, w)}{\partial w_{j}}+\cdots+\frac{\partial f(x(y, w)}{\partial x_{j}} \frac{\partial x_{n}(y, w)}{\partial w_{j}}\right) \\
& -\left(f(x(y, w)-y) \frac{\partial \lambda(y, w)}{\partial w_{j}} \equiv 0\right. \tag{89}
\end{align*}
$$

If the solution is such that $\lambda(\mathrm{y}, \mathrm{w})$ is not zero, then $(f(x(y, w)-y)$ is equal to zero and we can write

Combining equations 88 and 90 we obtain

If we then consider derivatives with respect to each of the $w_{j}$ we obtain

$$
\lambda\left(\begin{array}{cccc}
\frac{\partial^{2} f(x(y, w))}{\partial x_{1}^{2}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n} \partial x_{1}} & \frac{\partial f(x(y, w)}{\partial x_{1}}  \tag{92}\\
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{2}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n} \partial x_{2}} & \frac{\partial f(x(y, w)}{\partial x_{2}} \\
\vdots & \vdots & \vdots & \vdots \\
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{n}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n}^{2}} & \frac{\partial f(x(y, w)}{\partial x_{n}} \\
\frac{\partial f(x(y, w))}{\partial x_{1}} & \cdots & \frac{\partial f(x(y, w)}{\partial x_{n}} & 0
\end{array}\right)\left(\begin{array}{cccc}
\frac{\partial x_{1}(y, w)}{\partial w_{1}} & \frac{\partial x_{1}(y, w)}{\partial w_{2}} & \cdots & \frac{\partial x_{1}(y, w)}{\partial w_{n}} \\
\frac{\partial x_{2}(y, w)}{\partial w_{1}} & \frac{\partial x_{2}(y, w)}{\partial w_{2}} & \cdots & \frac{\partial x_{2}(y, w)}{\partial w_{n}} \\
\vdots & & & 0 \\
\frac{\partial x_{n}(y, w)}{\partial w_{1}} & \frac{\partial x_{n}(y, w)}{\partial w_{2}} & \cdots & \frac{\partial x_{n}(y, w)}{\partial w_{n}} \\
\frac{1}{\lambda} \frac{\partial \lambda(y, w)}{\partial w_{1}} & \frac{1}{\lambda} \frac{\partial \lambda(y, w)}{\partial w_{n}} & \cdots & \frac{1}{\lambda} \frac{\partial \lambda(y, w)}{\partial w_{n}}
\end{array}\right) \equiv\left(\begin{array}{ccc}
1 & 0 & \cdots \\
0 & 1 & \cdots \\
0 \\
0 & \vdots & \vdots \\
0 & 0 & \cdots \\
0
\end{array}\right)
$$

The matrix on the leftmost side of equation 92 is the just the bordered Hessian of the production function from equation 76 which is used in verifying that the extreme point is a minimum where $p=n$. We repeat it here for convenience.

$$
(-1)^{p}\left|\begin{array}{ccccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{1} \partial x_{p}} & \frac{\partial f}{\partial x_{1}} \\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{2} \partial x_{p}} & \frac{\partial f}{\partial x_{2}} \\
\vdots & \vdots & & \vdots & \vdots \\
\frac{\partial^{2} f}{\partial x_{p} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{p} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{p}^{2}} & \frac{\partial f}{\partial x_{p}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & \cdots & \frac{\partial f}{\partial x_{p}} & 0
\end{array}\right|>0
$$

3.5.1. Obtaining derivatives using Cramer's rule. We can obtain the various derivatives using Cramer's rule. For example to obtain $\frac{\partial x_{1}(y, w)}{\partial w_{1}}$ we would replace the first column of the bordered Hessian with the first column of matrix on the right of equation 91. To obtain $\frac{\partial x_{2}(y, w)}{\partial w_{1}}$ we would replace the second column of
the bordered Hessian with the first column of matrix on the right of equation 91. To obtain $\frac{\partial x_{2}(y, w)}{\partial w_{j}}$, we would replace the second column of the bordered Hessian with the jth column of matrix on the right of equation 91 and so forth.

Consider for example the case of two variable inputs. The bordered Hessian is given by

$$
H_{B}=\left[\begin{array}{ccc}
\frac{\partial^{2} f}{\partial x^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}}  \tag{93}\\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & 0
\end{array}\right]
$$

The determinant of the $\mathrm{H}_{B}$ in equation 93 is often referred to as F and is given by

$$
\begin{align*}
F & =0 \cdot(-1)^{6} \cdot\left|\begin{array}{cc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} \\
\frac{2^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{\prime} f}{\partial x_{2}^{2}}
\end{array}\right|+\frac{\partial f}{\partial x_{2}} \cdot(-1)^{5} \cdot\left|\begin{array}{cc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial f}{\partial x_{1}} \\
\frac{\partial^{\prime} f}{\partial x_{2} \partial x_{1}} & \frac{\partial f}{\partial x_{2}}
\end{array}\right|+\frac{\partial f}{\partial x_{1}} \cdot(-1)^{4} \cdot\left|\begin{array}{cc}
\frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}} \\
\frac{\partial^{\prime} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}}
\end{array}\right| \\
& =\frac{\partial f}{\partial x_{1}} \cdot\left|\begin{array}{cc}
\frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}} \\
\frac{\partial^{\prime} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}}
\end{array}\right|-\frac{\partial f}{\partial x_{2}} \cdot\left|\begin{array}{cc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial f}{\partial x_{1}} \\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial f}{\partial x_{2}}
\end{array}\right|  \tag{94}\\
& =\frac{\partial f}{\partial x_{1}} \cdot\left[\frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} \frac{\partial f}{\partial x_{2}}-\frac{\partial f}{\partial x_{1}} \frac{\partial^{2} f}{\partial x_{2}^{2}}\right]-\frac{\partial f}{\partial x_{2}} \cdot\left[\frac{\partial^{2} f}{\partial x_{1}^{2}} \frac{\partial f}{\partial x_{2}}-\frac{\partial f}{\partial x_{1}} \frac{\partial^{2} f}{\partial x_{2} \partial x_{1}}\right] \\
& =2 \frac{\partial f}{\partial x_{1}} \frac{\partial f}{\partial x_{2}} \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}}-\left(\frac{\partial f}{\partial x_{1}}\right)^{2} \frac{\partial^{2} f}{\partial x_{2}^{2}}-\left(\frac{\partial f}{\partial x_{2}}\right)^{2} \frac{\partial^{2} f}{\partial x_{1}^{2}} \\
& =2 f_{1} f_{2} f_{12}-f_{1}^{2} f_{22}-f_{2}^{2} f_{11}
\end{align*}
$$

We know that this expression is positive by the quasiconcavity of $f$ or the second order conditions for cost minimization. We can determine $\frac{\partial x_{1}}{\partial w_{2}}$ by replacing the first column of F with the vector $\left(\begin{array}{l}0 \\ 1 \\ 0\end{array}\right)$. Doing so we obtain

$$
\left[\begin{array}{ccc}
0 & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}}  \tag{95}\\
1 & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}} \\
0 & \frac{\partial f}{\partial x_{2}} & 0
\end{array}\right]
$$

The determinant of the matrix in equation 95 is easy to compute and is given by

$$
\begin{align*}
& \frac{\partial f}{\partial x_{2}} \cdot(-1)^{5} \cdot\left|\begin{array}{cc}
0 & \frac{\partial f}{\partial x_{1}} \\
1 & \frac{\partial f}{\partial x_{2}}
\end{array}\right|  \tag{96}\\
= & -\frac{\partial f}{\partial x_{2}} \cdot\left(-\frac{\partial f}{\partial x_{1}}\right)=\frac{\partial f}{\partial x_{1}} \cdot \frac{\partial f}{\partial x_{2}} \geq 0
\end{align*}
$$

Given that F is positive, this implies that $\frac{\partial x_{1}}{\partial w_{2}}$ is positive. To find $\frac{\partial x_{2}}{\partial w_{2}}$ we replace the second column of F with the vector $\left(\begin{array}{l}0 \\ 1 \\ 0\end{array}\right)$.

$$
\left[\begin{array}{ccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & 0 & \frac{\partial f}{\partial x_{1}}  \tag{97}\\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & 1 & \frac{\partial f}{\partial x_{2}} \\
\frac{\partial f}{\partial x_{1}} & 0 & 0
\end{array}\right]
$$

The determinant of the matrix in equation 97 is also easy to compute and is given by

$$
\frac{\partial f}{\partial x_{1}} \cdot(-1)^{4} \cdot\left|\begin{array}{cc}
0 & \frac{\partial f}{\partial x_{1}}  \tag{98}\\
1 & \frac{\partial f}{\partial x_{2}}
\end{array}\right|=\frac{\partial f}{\partial x_{1}} \cdot\left(-\frac{\partial f}{\partial x_{1}}\right)=-\left(\frac{\partial f}{\partial x_{1}}\right)^{2} \leq 0
$$

Given that F is positive, this implies that $\frac{\partial x_{2}}{\partial w_{2}}$ is negative.
3.5.2. Obtaining derivatives by matrix inversion. We can also solve equation 92 directly for the response function derivatives by inverting the bordered Hessian matrix. This then implies that

For example $\frac{\partial x_{2}}{\partial w_{2}}$ would be the $(2,2)$ element of the inverse of the bordered Hessian. We can determine this element using the formula for the inverse of a matrix involving the determinant of the matrix and the adjoint of the matrix. The adjoint of the matrix A denoted adj (A) or $\mathrm{A}^{+}$is the transpose of the matrix obtained from A by replacing each element $\mathrm{a}_{i j}$ by its cofactor $\mathrm{A}_{i j}$. For a square nonsingular matrix A , its inverse is given by

$$
\begin{equation*}
A^{-1}=\frac{1}{|A|} A^{+} \tag{100}
\end{equation*}
$$

We can compute $(2,2)$ element of the inverse of the bordered Hessian from the cofactor of that element divided by the determinant of the bordered Hessian which we have denoted F. It is clear from section 3.2.2 that $\mathrm{F}_{22}$ (the cofactor of the $(2,2)$ element) and F have opposite signs so that the partial derivative will be negative. Given that the Hessian is a symmetric matrix, it is also clear that $\frac{\partial x_{i}}{\partial w_{j}}=\frac{\partial x_{j}}{\partial w_{i}}$.

Consider the two variable case with bordered Hessian

$$
H_{B}=\left[\begin{array}{ccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}}  \tag{101}\\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}} & 0
\end{array}\right]
$$

We found the determinant of $\mathrm{H}_{B}$ in equation 94, i.e,

$$
\begin{align*}
\operatorname{det} H_{B}=F & =2 \frac{\partial f}{\partial x_{1}} \frac{\partial f}{\partial x_{2}} \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}}-\left(\frac{\partial f}{\partial x_{1}}\right)^{2} \frac{\partial^{2} f}{\partial x_{2}^{2}}-\left(\frac{\partial f}{\partial x_{2}}\right)^{2} \frac{\partial^{2} f}{\partial x_{1}^{2}}  \tag{102}\\
& =2 f_{1} f_{2} f_{12}-f_{1}^{2} f_{22}-f_{2}^{2} f_{11}
\end{align*}
$$

Each element of the inverse will have this expression as a denominator. To compute the numerator of the $(1,1)$ element of the inverse we compute the cofactor of the $(1,1)$ element of the bordered Hessian. This is given by

$$
\begin{align*}
& (-1)^{2} \cdot\left|\begin{array}{cc}
\frac{\partial^{2} f}{\partial x_{2}^{2}} & \frac{\partial f}{\partial x_{2}} \\
\frac{\partial f}{\partial x_{2}} & 0
\end{array}\right|  \tag{103}\\
= & -\left(\frac{\partial f}{\partial x_{2}}\right)^{2}
\end{align*}
$$

To compute the numerator of the $(1,2)$ element of the inverse we compute the cofactor of the $(2,1)$ element of the bordered Hessian. This is given by

$$
\begin{align*}
& (-1)^{3} \cdot\left|\begin{array}{cc}
\frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial f}{\partial x_{1}} \\
\frac{\partial f}{\partial x_{2}} & 0
\end{array}\right|  \tag{104}\\
= & \frac{\partial f}{\partial x_{1}} \frac{\partial f}{\partial x_{2}}
\end{align*}
$$

To compute the numerator of the $(3,2)$ element of the inverse we compute the cofactor of the $(2,3)$ element of the bordered Hessian. This is given by

$$
\begin{align*}
& (-1)^{5} \cdot\left|\begin{array}{cc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} \\
\frac{\partial f}{\partial x_{1}} & \frac{\partial f}{\partial x_{2}}
\end{array}\right| \\
= & (-1)\left(\frac{\partial^{2} f}{\partial x_{1}^{2}} \frac{\partial f}{\partial x_{2}}-\frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} \frac{\partial f}{\partial x_{1}}\right)  \tag{105}\\
= & \frac{\partial f}{\partial x_{1}} \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}}-\frac{\partial f}{\partial x_{2}} \frac{\partial^{2} f}{\partial x_{1}^{2}}
\end{align*}
$$

To compute the numerator of the $(3,3)$ element of the inverse we compute the cofactor of the $(3,3)$ element of the bordered Hessian. This is given by

$$
\begin{align*}
& (-1)^{6} \cdot\left|\begin{array}{cc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} \\
\frac{\partial f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}}
\end{array}\right| \\
= & \frac{\partial^{2} f}{\partial x_{1}^{2}} \frac{\partial f}{\partial x_{2}^{2}}-\frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}}  \tag{106}\\
= & \frac{\partial^{2} f}{\partial x_{1}^{2}} \frac{\partial f}{\partial x_{2}^{2}}-\left(\frac{\partial^{2} f}{\partial x_{1} \partial x_{2}}\right)^{2}
\end{align*}
$$

This expression will be positive or zero for a concave function. We can now start to fill in the inverse matrix of the bordered Hessian.

$$
\begin{align*}
& =\frac{\left[\begin{array}{ccc}
-f_{2}^{2} & f_{1} f_{2} & f_{2} f_{12}-f_{1} f_{22} \\
f_{1} f_{2} & -f_{1}^{2} & f_{1} f_{12}-f_{2} f_{11} \\
? & f_{1} f_{12}-f_{2} f_{11} & f_{11} f_{22}-f_{12}^{2}
\end{array}\right]}{2 f_{1} f_{2} f_{12}-f_{1}^{2} f_{22}-f_{2}^{2} f_{11}} \tag{107}
\end{align*}
$$

If we postmultiply this matrix by $\left[\begin{array}{ll}1 & 0 \\ 0 & 1 \\ 0 & 0\end{array}\right]$ we can obtain the comparative statics matrix.

For example, $\frac{\partial x_{2}}{\partial w_{1}}$ is equal to
or $\frac{\partial \lambda}{\partial w_{1}}$ is equal to $\frac{\frac{\partial f}{\partial x_{2}} \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}}-\frac{\partial f}{\partial f_{1}} \frac{\partial^{2} f}{\partial x_{2}} f_{12}-f_{1}^{2} f_{22}-f_{2}^{2} f_{11}}{\text {. }}$.
3.6. The impact of output on input demands. If we differentiate the first order conditions in equation 84 with respect to y instead of with respect to $\mathrm{w}_{j}$ the system in equation 91 would be as follows.

$$
\lambda\left(\begin{array}{ccccccc}
\frac{\partial^{2} f(x(y, w))}{\partial x_{1}^{2}} & \frac{\partial^{2} f(x(y, w)}{\partial x_{2} \partial x_{1}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{j} \partial x_{1}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n} \partial x_{1}} & \frac{\partial f(x(y, w)}{\partial x_{1}}  \tag{110}\\
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{2}} & \frac{\partial^{2} f(x(y, w)}{\partial x_{2}^{2}} & \ldots & \frac{\partial^{2} f(x(y, w)}{\partial x_{j} \partial x_{2}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n} \partial x_{2}} & \frac{\partial f(x(y, w)}{\partial x_{2}} \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \\
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{j}} & \frac{\partial^{2} f(x(y, w)}{\partial x_{2} \partial x_{j}} & \ldots & \frac{\partial^{2} f(x(y, w)}{\partial x_{j}^{2}} & \ldots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n} \partial x_{j}} & \frac{\partial f(x(y, w)}{\partial x_{j}} \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \\
\frac{\partial x_{2}(y, w)}{\partial y} \\
\frac{\partial^{2} f(x(y, w))}{\partial x_{1} \partial x_{n}} & \frac{\partial^{2} f(x(y, w)}{\partial x_{2} \partial x_{n}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{j} \partial x_{n}} & \cdots & \frac{\partial^{2} f(x(y, w)}{\partial x_{n}^{2}} & \frac{\partial f(x(y, w)}{\partial x_{n}} \\
\frac{\partial f(x(y, w))}{\partial x_{1}} & \frac{\partial f(x(y, w)}{\partial x_{2}} & \cdots & \frac{\partial f(x(y, w)}{\partial x_{j}} & \cdots & \frac{\partial f(x(y, w)}{\partial x_{n}} & 0
\end{array}\right)\left(\begin{array}{c}
\frac{\partial x_{1}(y, w)}{0} \\
\frac{\partial x_{j}(y, w)}{\partial y} \\
\frac{\partial x_{n}(y, w)}{\partial y} \\
\frac{1}{\lambda} \frac{\partial \lambda(y, w)}{\partial y}
\end{array}\right)\left(\begin{array}{c}
0 \\
0 \\
\vdots \\
0 \\
1
\end{array}\right)
$$

Consider the impact of an increase in output on marginal cost. To investigate this response replace the last column of the bordered Hessian with the right hand side of equation 110. This will yield

We can then find $\frac{1}{\lambda} \frac{\partial \lambda(y, w)}{\partial y}$ using Cramer's rule noting that $\frac{1}{\lambda}$ appears on both sides of the expression for $\frac{\partial \lambda(y, w)}{\partial y}$ and so can be ignored.

An alternative way to investigate the impact of output on marginal cost is to totally differentiate the first order conditions as follows.

$$
\begin{align*}
& -\lambda \Sigma_{j=1}^{n} \frac{\partial^{2} f}{\partial x_{i} \partial x_{j}} d x_{j}-\frac{\partial f}{\partial x_{i}} d \lambda=0  \tag{112}\\
& \Rightarrow \frac{\partial f}{\partial x_{i}}=-\Sigma \lambda \frac{\partial^{2} f}{\partial x_{i} \partial x_{j}} \frac{d x_{j}}{d \lambda}
\end{align*}
$$

Now substitute into the differential of the constraint by replacing $\frac{\partial f}{\partial x_{i}}$ in

$$
\begin{equation*}
d y=\Sigma \frac{\partial f}{\partial x_{i}} d x_{i} \tag{113}
\end{equation*}
$$

with the above expression to obtain

$$
\begin{equation*}
d y d \lambda=-\lambda \Sigma_{i} \Sigma_{j=1}^{n} \frac{\partial^{2} f}{\partial x_{i} \partial x_{j}} d x_{j} d x_{i}>0 \tag{114}
\end{equation*}
$$

because $\lambda>0$ and the summation is just the quadratic form for the concave function f which is always negative. Because changes in marginal cost and output have the same signs, marginal cost is increasing as a function of output. Thus with concave production, marginal cost is always upward sloping (Shephard [16, p. 83; 88-92]). For further discussion of this traditional approach see Allen [1, p.502-504], Ferguson [10, p. 109; 137-140], or Samuelson [15, p. 64-65].

## 4. Cost Function Duality

We can show that if we have an arbitrarily specified cost function that satisfies the conditions in section 2.3, we can construct from it a reasonable technology (specifically the input requirement function) that satisfies the conditions we specified in section 1.1.1 and that would generate the specified cost function.
4.1. Constructing the input requirement set from the cost function. Let $\mathrm{V}^{*}(\mathrm{y})$ be defined as

$$
\begin{align*}
V^{*}(y) & \equiv\{x: w x \geq C(y, w), \forall w>0\} \\
& \equiv \cap w>0\{x: w x \geq C(y, w)\} \tag{115}
\end{align*}
$$

To see the intuition of why we can construct $\mathrm{V}(\mathrm{y})$ in this way consider figure 6

Figure 6. Half-Spaces and Input Requirement Set

If we pick a particular set of prices then $\mathrm{V}^{*}(\mathrm{y})$ consists of all points above the line that is tangent to $\mathrm{V}(\mathrm{y})$ at the optimal input combination. The equation $\{x): w x \geq C(y, w)$ for a particular set of prices defines a line in $\mathrm{R}^{2}$ or a hyperplane in $\mathrm{R}^{n}$. Points above the line are considered to be in $\mathrm{V}^{*}(\mathrm{y})$. Now pick a different set of prices with $\mathrm{w}_{2}$ higher and construct a different line as in figure 7 . The number of points in $V^{*}(y)$ is now less than before. If we add a third set of prices with $w_{2}$ lower than in the original case as in figure 8, we can reduce the size of $V^{*}(y)$ even more. Continuing in this fashion we can recover $\mathrm{V}(\mathrm{y})$. This is an application of what is often called Minkowski's theorem.

Theorem 3. Suppose $V(y)$ satisfies properties 1,2 (strong), 5 and 7. If $y \geq 0$ and is an element of the domain of $V$ then $V(y)=$ $V^{*}(y)$
